Primary support for the subproject and the subproject's principal investigator may have been provided by other sources, including other NIH sources. The Total Cost listed for the subproject likely represents the estimated amount of Center infrastructure utilized by the subproject, not direct funding provided by the NCRR grant to the subproject or subproject staff. The ability to control protein stability is essential in the design and engineering of protein therapeutics. The balance between protein stability, that promotes its effectiveness and half-life, and protein activity, that is essential for its pharmaceutical utility, is a critical facet of the drug discovery and development process. Continued advances in protein engineering provide a means to modulate protein stability, increasing the half-life or even increasing the activity of therapeutic proteins, in turn providing a valuable method for increasing the therapeutic potential of existing drug candidates and for the discovery of new protein therapeutics. The overall goal of this project is to create and apply methods for engineering protein stability in order to enhance its therapeutic utility. The focus of this proposal is on the design, characterization, and optimization of a novel class of protein foldases based on p23, a protein that binds to protein aggregates in a specific and reversible manner. These foldases will be created by replacing the p23 binding domain of chaperone-like foldases with a p23 binding domain, and by altering the surface amino acid composition of the p23 binding domain to modulate protein stability. The biophysical properties and structure of the foldases will be characterized to optimize stability and protein activity, and to gain insight into the relationship between protein stability and structure. In addition, a high
